

# Git Foundations for the AI Era

From 'Ctrl+Z' to Time Travel: How to protect, experiment, and showcase your work.

# A Project Folder Has No Undo Button

## Case File

### The Toy Story 2 Disaster (1998)

A Pixar employee accidentally ran a delete command. 90% of the movie vanished in seconds.

The backup system failed. The film was only saved because one employee, Galyn Susman, had a copy on her home computer to care for her newborn.

Open a Google Doc, delete a paragraph, press Ctrl+Z—it returns. Open a project folder, ask an AI agent to reorganize it, and watch it mangle 12 files. Press Ctrl+Z—nothing happens.

**“Ctrl+Z works for one file. Git works for your life’s work.”**

# The Camera: Commits Are Snapshots, Not Saves

A standard “Save” overwrites the previous version. A “Commit” is a photograph of your *entire* project folder at a specific moment.

Git photographs your entire project, not individual files.

## The Scenario:

Sarah spends two hours on a budget spreadsheet. She tries a new layout and accidentally overwrites the file.

Without Git, the old version is gone forever. With Git, she simply rewinds to the previous snapshot.

# The Suitcase: Why We Don't 'Add Everything'

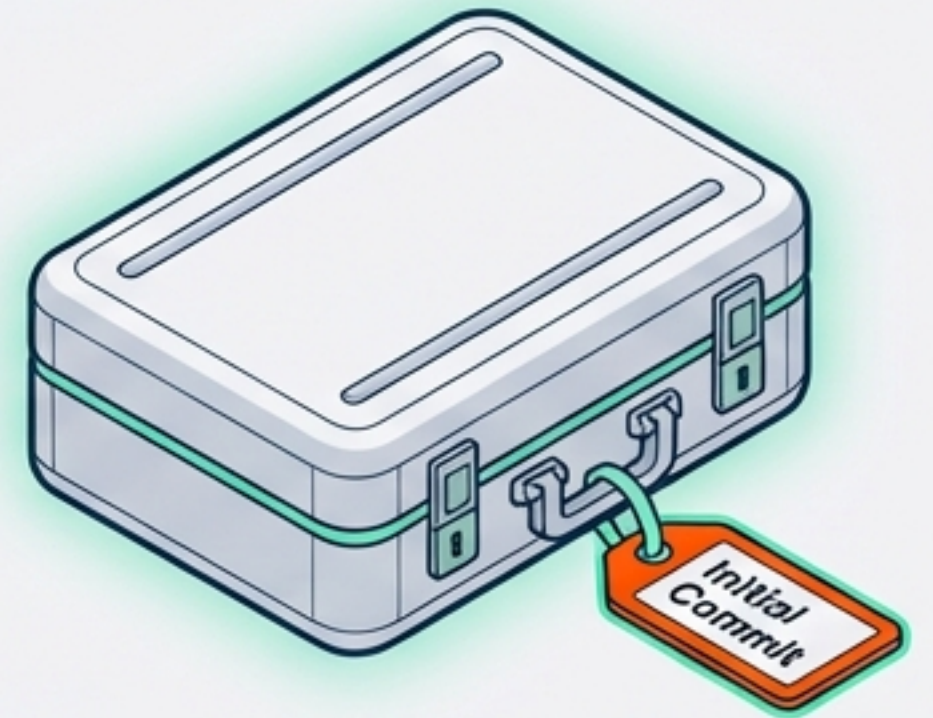

You might have personal notes, privacy-sensitive data, or broken code on 'the bed.' You only commit what is ready for the permanent record.

**The Bed**  
(Working Directory)

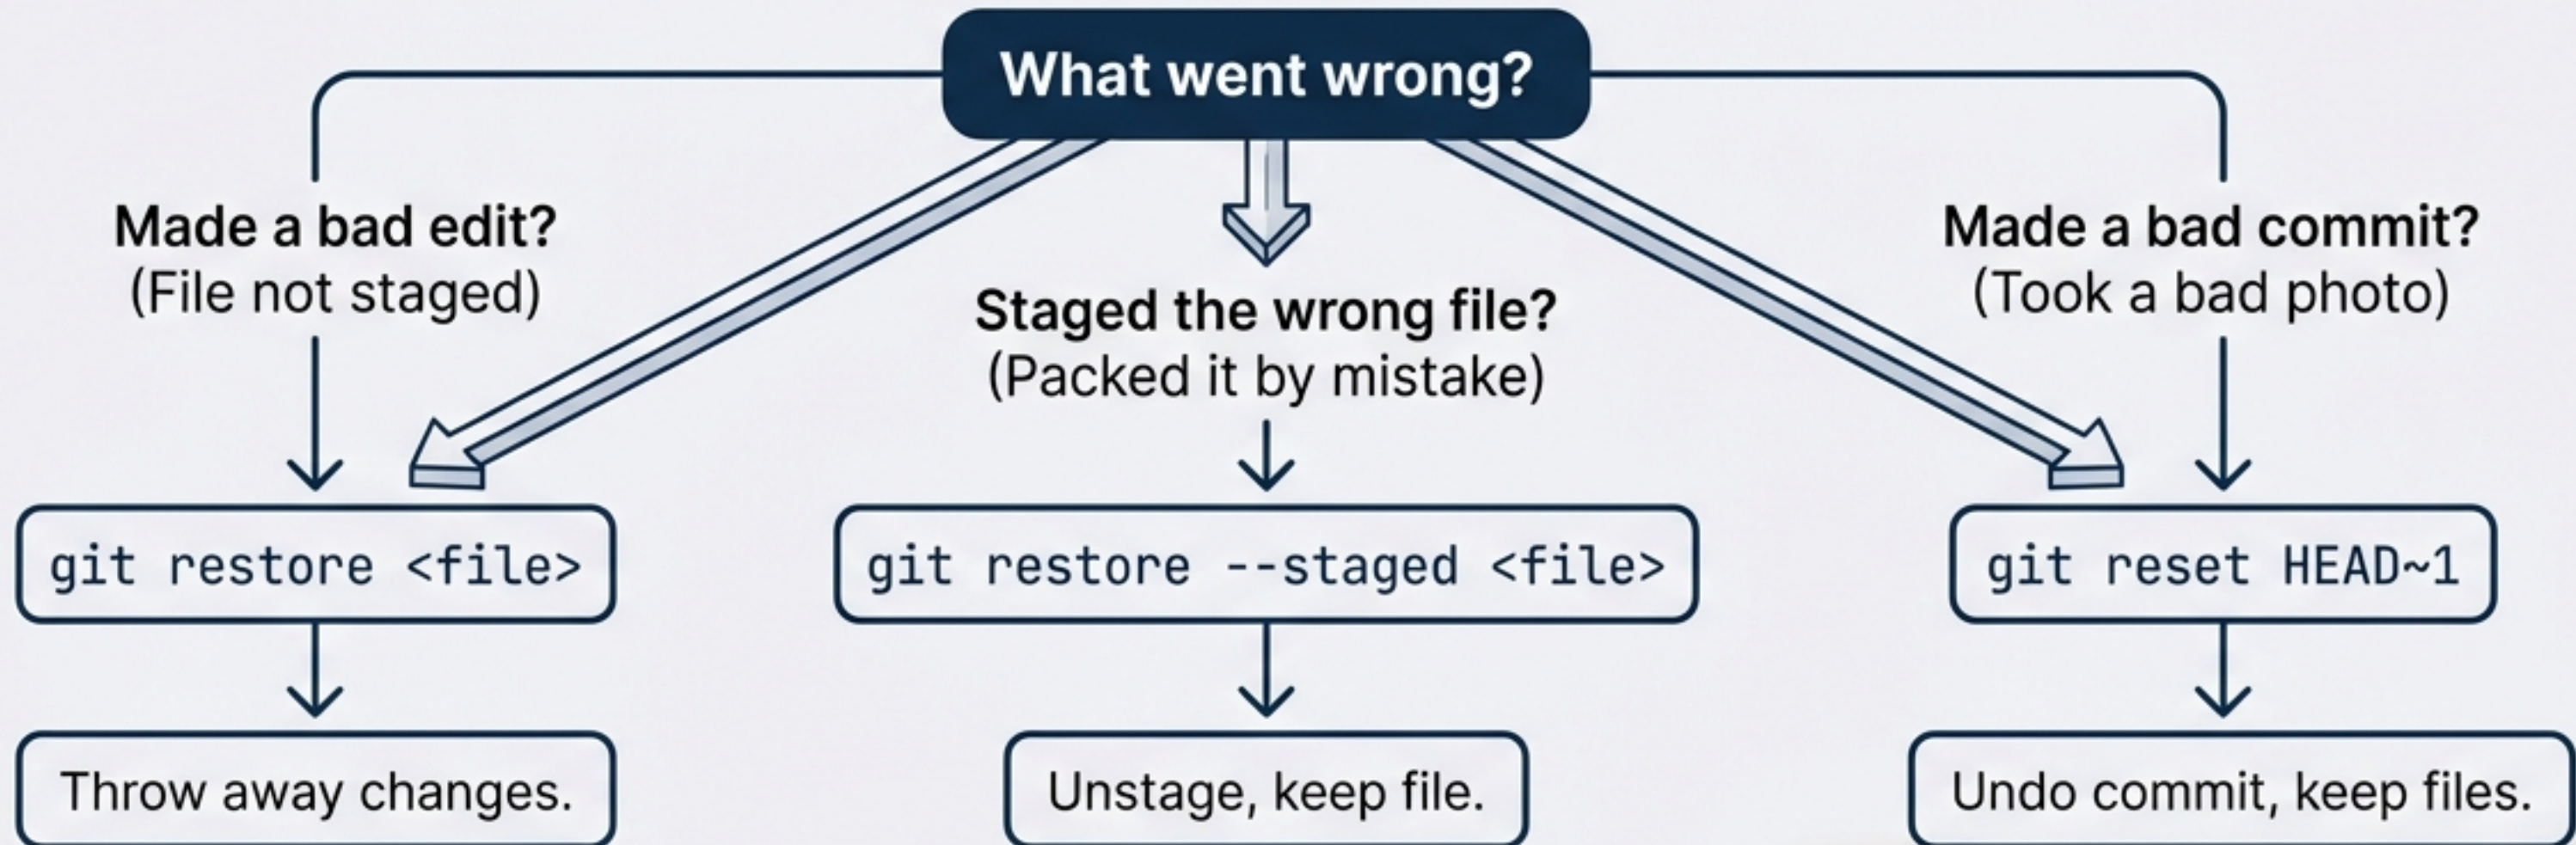

**The Open Suitcase**  
(Staging Area)

**The Closed Suitcase**  
(Commit)

# The Panic Button: Three Levels of Undo

## The Nuclear Option:

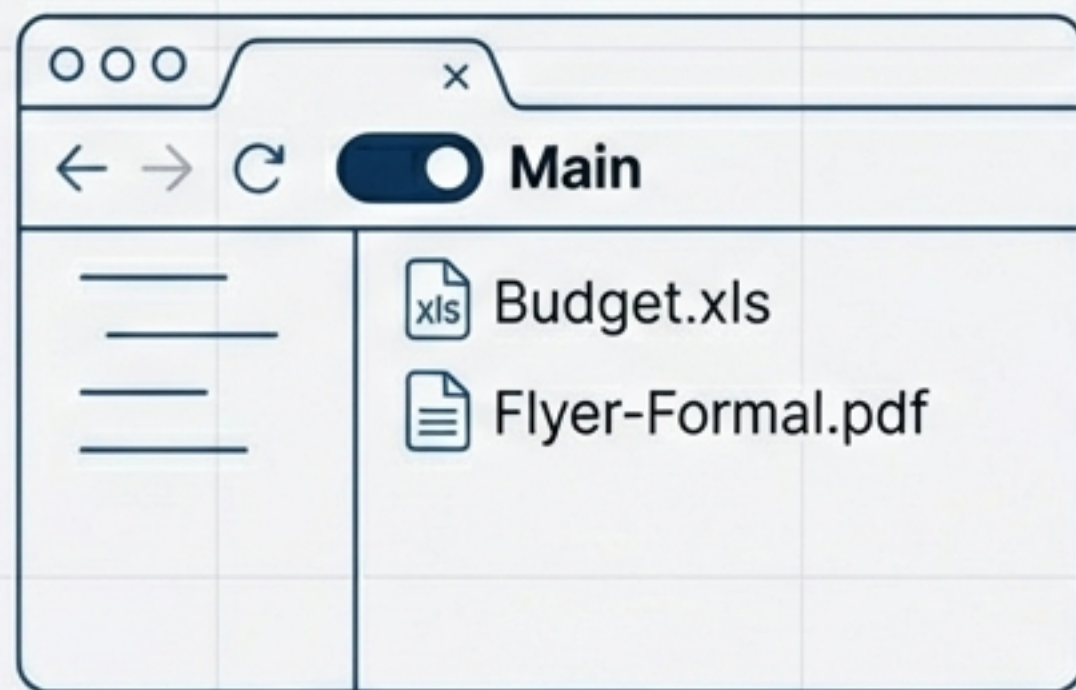

`git reset --hard` deletes the commit AND the files. It has no confirmation dialog. Use with extreme caution.

# Parallel Universes: Testing Risky Ideas Safely

Sarah needs a "Formal" flyer for sponsors and a "Casual" one for social media. Instead of making file copies like `flyer_final_v2.txt`, she creates a Branch. She can mess up the casual version without ever touching the formal project.

# The Magic Trick: Switching Contexts

Main Branch in Inter

git switch

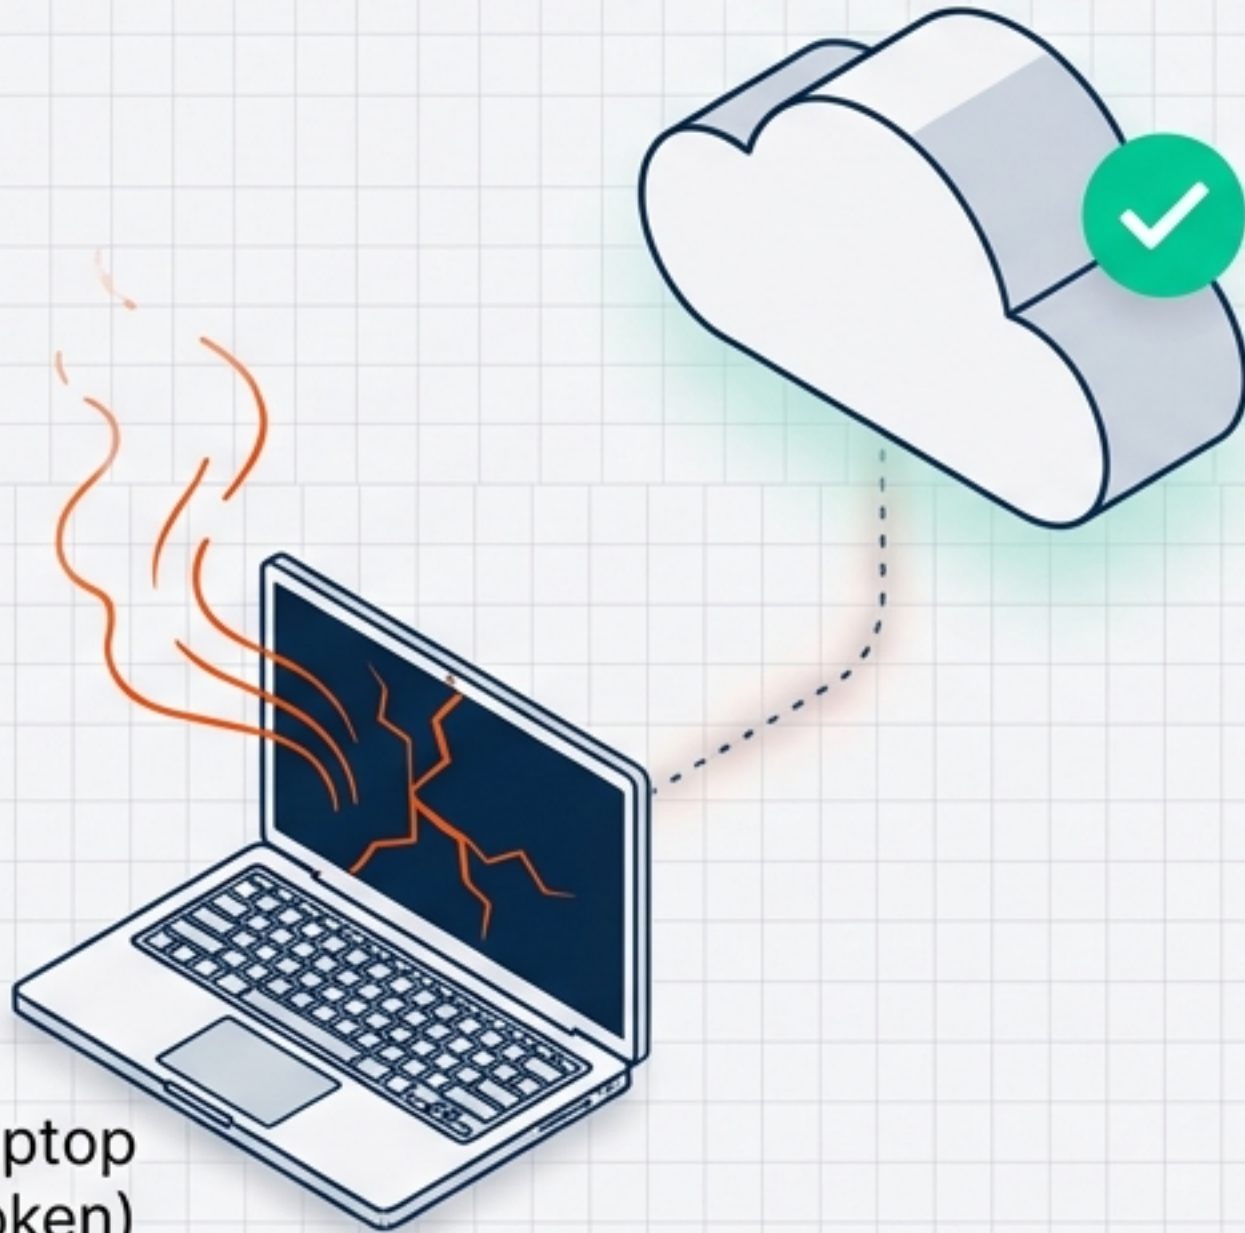

Feature Branch in Inter

## Workflow Steps

- **Create Branch:** `git switch -c feature/new-idea``
- **Make Changes:** Edit files safely.
- **Switch to Main:** Return to safety.
- **Merge:** Bring the winner into the main timeline.

**Branches let you live in two timelines at once—and only keep the one that works. Files literally disappear and reappear when you switch.**

# The Cloud: A Backup You've Never Tested Doesn't Exist

**GitHub**

Cloud Vault (Safe)

## The GitLab Database Disaster (2017)

An engineer accidentally deleted the production database. Five different backup systems failed. They lost 6 hours of user data.

**Git** is the tool on your computer.  
**GitHub** is the cloud vault.

If Sarah's project is only on her laptop, it's gone.  
If it's on GitHub, she can recover it in seconds.

# Security Critical: The .gitignore Rule

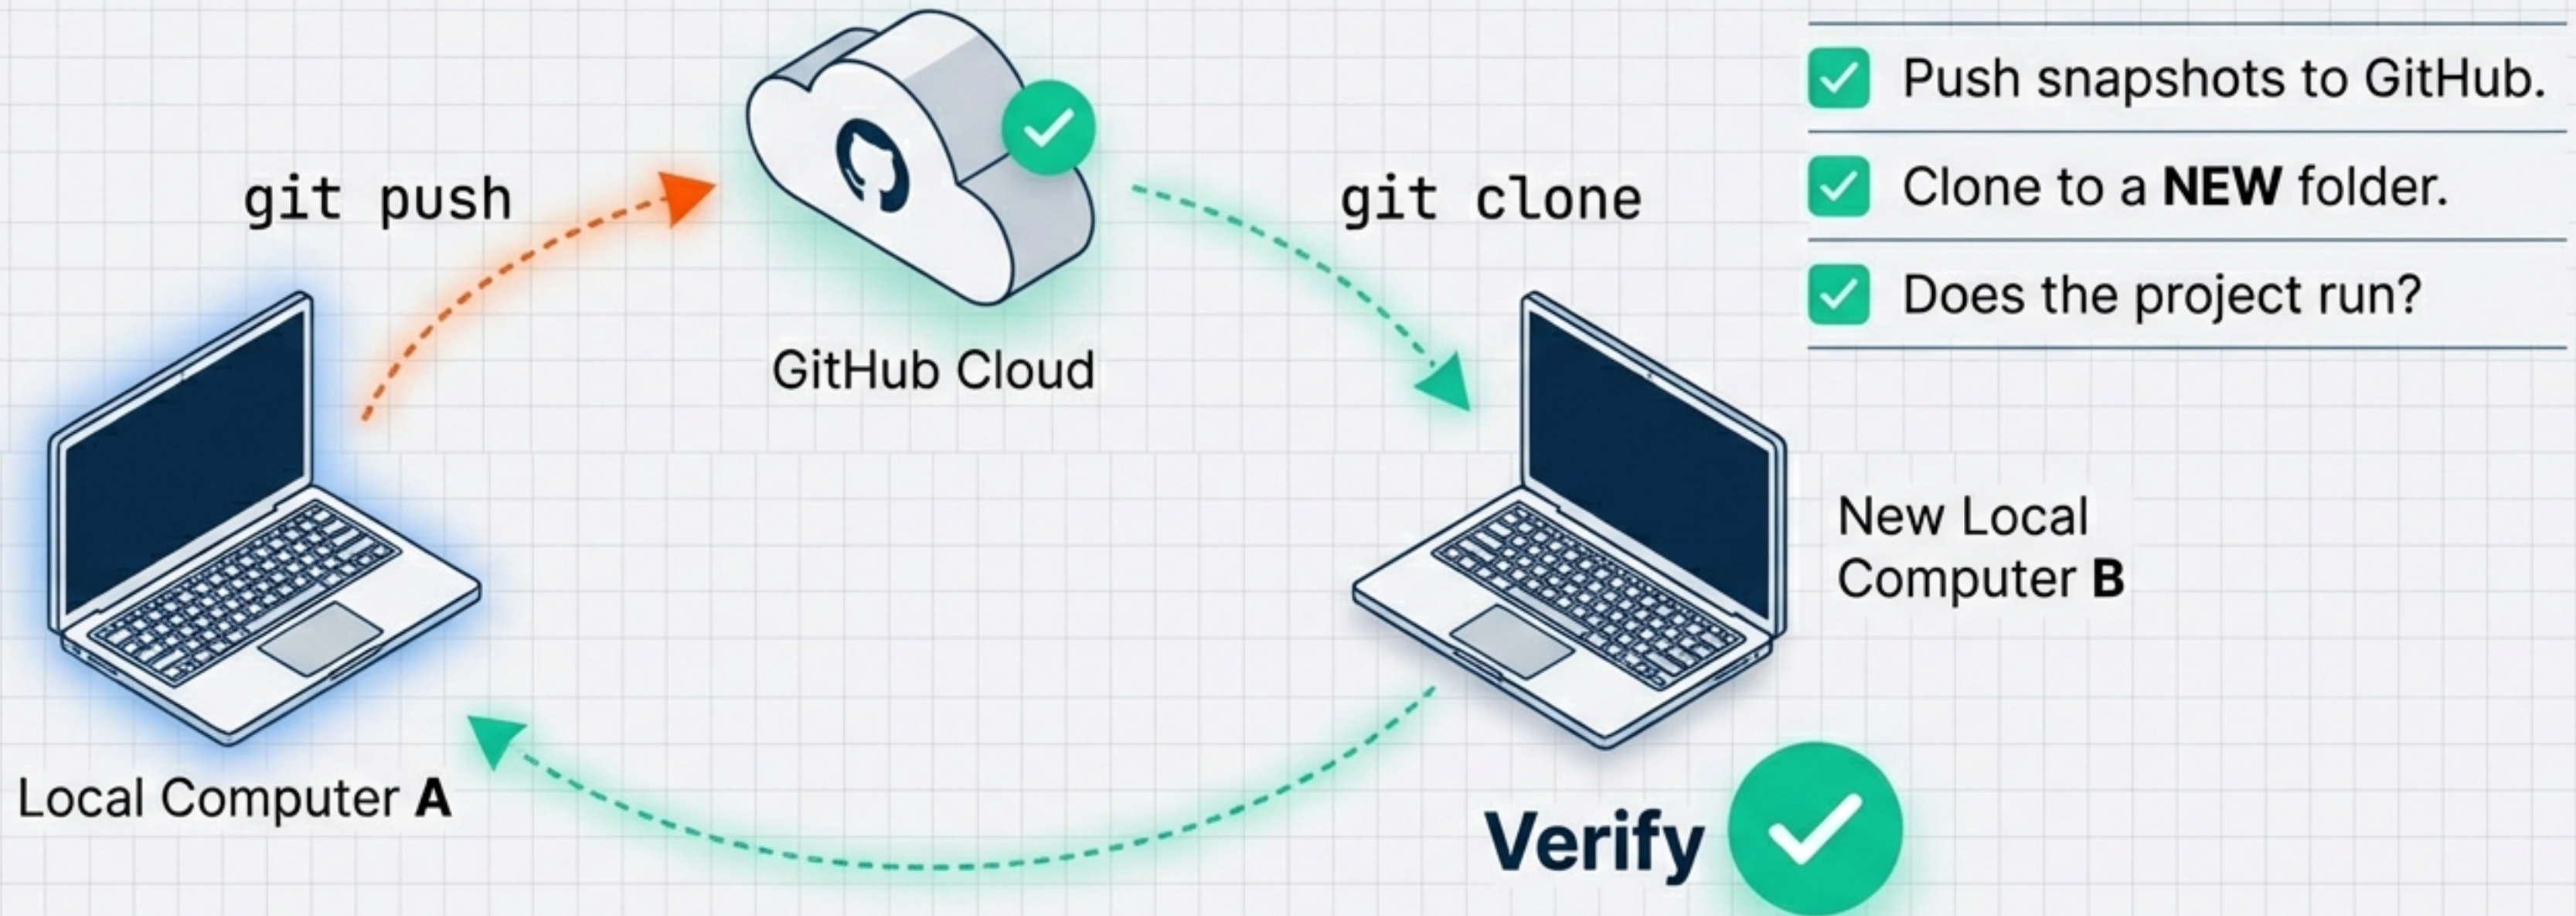

**The Danger:** Sarah accidentally committed her Stripe API key. Even if she deletes the file later, the key remains in the history for anyone to find.

**The Rule:** Configure .gitignore BEFORE your first push.

**What to ignore:** API keys, system files, passwords.

# Verification: The Clone Test

**The push/clone cycle is the verification step most people skip.**

# The 'Are You Sure?' Dialog: Pull Requests

## Merge Pull Request

### The Problem

Sarah overwrote Maya's formatting because she merged without looking. "I wrote it, so it must be fine" is a dangerous instinct.

### Solution

A Pull Request (PR) forces a pause. It asks: "Here are the changes. Review them before they become permanent."

### Context Note:

The 2012 Knight Capital incident (massive financial loss) was caused by unreviewed deployment changes.

# Reading the Diff & Declaring AI Intent

```
Diff Inamote ...  
@@ -9,2, -3 @@  
- def calculate_budget(income, expenses):  
-     total = income - expenses  
-     return total  
+ def calculate_budget(income, expenses):  
+     """Calculates net budget with validation."""  
+     if expenses < 0 or income < 0:  
+         raise ValueError("Invalid input")  
+  
+     total = income - expenses  
+     return total
```

Red = Removed

Green = Added

**\*\*Description\*\***: Refactored the budget calculator.

**\*\*AI Assistance\*\***: Boilerplate generated by Claude, logic verified by me.

Green = Added

**The Golden Rule —  
Never merge what you don't  
understand—even if you wrote it.**

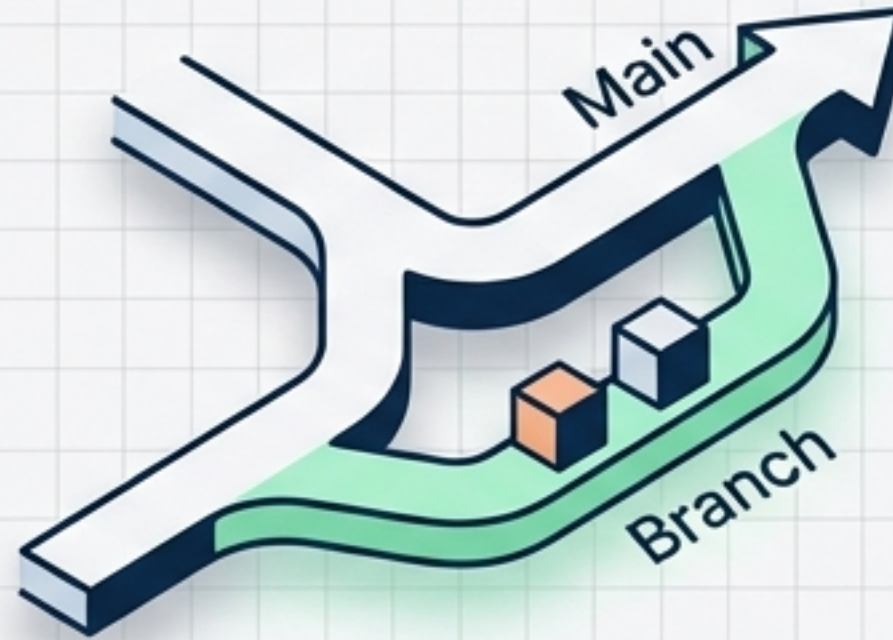

- ✓ What changed?
- ✓ How was it tested?
- ✓ What role did AI play? (Transparency is a professional strength).

# The 3 Professional Patterns

## Commit Before Experimenting

The Safety Net. Save state before asking the agent to try something risky.

## Branch-Test-Merge

The Sandbox. Isolate messy work so main stays clean.

## Push for Backup

The Vault. Push after every meaningful step.

Synthesizing everything into daily habits.

# Speaking 'Git' to Your Agent

You don't need to memorize syntax. You need to communicate intent.

## Your Intent (Chat Interface)

I messed up, go back.

Let's try a risky idea.

Make sure my backup works.

## Agent Action (Terminal Code)

```
git restore
```

```
git switch -c experiment
```

```
git clone
```

The agent handles the command. You provide the strategy.

# From Fear to Time Travel

You started hoping Ctrl+Z works. Now you have a system to Snapshot history, Create parallel universes, and Teleport work to the cloud.

**Trust the system, not your memory.**
